1 Electron beam setup

1.1 Charatarization of a working CRT

HAMEG HM507 oscilloscopes [1] were used for testing purposes. These contain a D14-363GY/123[2] CRT hereinafter abbreviated as ‘D14’, ‘tube’, or ‘CRT’. Although the HM507 has only a bandwidth of 0 MHz to 50 MHz, which is not sufficient for the hyperfine splitting frequency of 461.7 MHz of ^{39}K , it was used nevertheless because of its simple construction and availability. A schematic view of the device is shown in fig. 1.1 with the back pin arrangement in fig. 1.2.

The voltages and currents of the necessary pins to drive the CRT were measured using a 2.5 kV probe with an attenuation ratio of and are summarized in table 1.1. It was not possible to measure pin g3 directly. Therefore a HVPS (section 1.2) was used to set a voltage and the beam diameter was observed. The best focus was achieved with the voltage mentioned in the table. The voltage offset of x-, and y-plates was not possible to measure directly, since it varies with time to draw the necessary image on the phosphor screen. The given values in table 1.1 are the mean of the minimum and maximum measured voltage. The deflection coefficient is summarized in table 1.2.

1.2 High Voltage Power Supply HVPS

To produce high dc voltages to drive the CRT, 4 HCP 14-6500[3] power supplies were used. They were named ‘HVPS 1’ to ‘HVPS 4’ and can provide up to ± 6.5 kVdc and 2 mA. To connect the output to the CRT pins, BNC cables were refitted with a save high voltage (SHV) connector on one side while on the other end the BNC connector was kept. The output was measured with a 6 kV probe and the ripple was determined to be between 116 mV and 204 mV. The breakdown voltages is around 3 kV.

1.3 CRT wiring

A schematic of the supplied power is shown in fig. 1.3. A small ac or dc voltage is necessary to drive the heater filament. This part of the setup is explained in section 1.4.
